Test 1

This test consists simply of pulsing one electrolytic cap into another one through a multi filer coil. Power for logic of mosfets was separated from power being tested.

Coil – Quad filer (Four wires/coils on one coil), 26 gauge magnet wire, 800 turns

Coil1 – Input

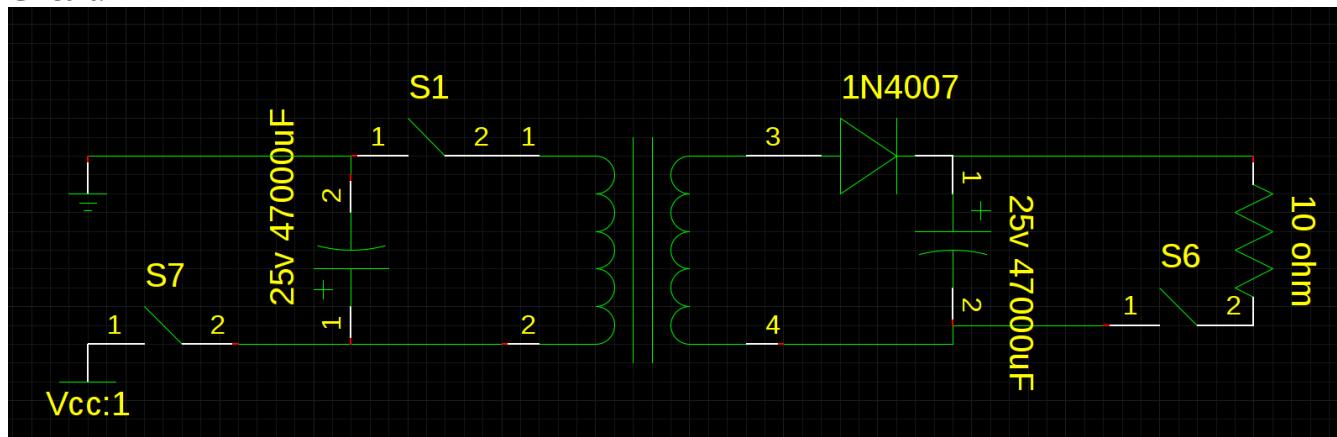

Coil2 – Output

Coil3&4 – not used, ends hanging in air

Input Cap – 25v 47000uF Electrolytic

Output Cap – 25v 47000uF Electrolytic

Circuit:

Frequency scan test sequence:

S7 & S6 were closed for 6 seconds

Voltage readings were taken from both caps and recorded

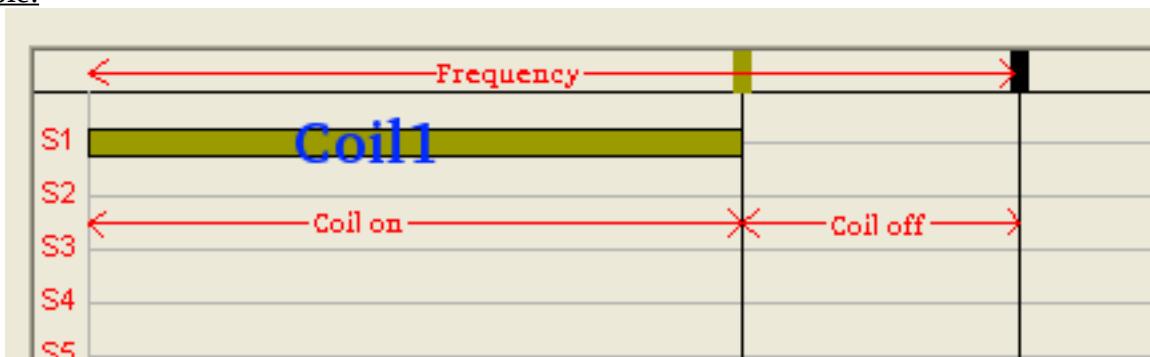

S1 was pulsed at a specified duty load at X frequency for 40 secs

Voltage readings were taken from both caps again and recorded

X was raised by 50 hertz

Process was repeated 100 times

Example:

Formulas:

COP was calculated by (Output Joules)/(Input Joules)

Input joules were calculated by $((A_2 * 0.047) * A_2) / 2 - ((C_2 * 0.047) * C_2) / 2$

A₂ = Input start cap voltage

C₂ = Input end cap voltage

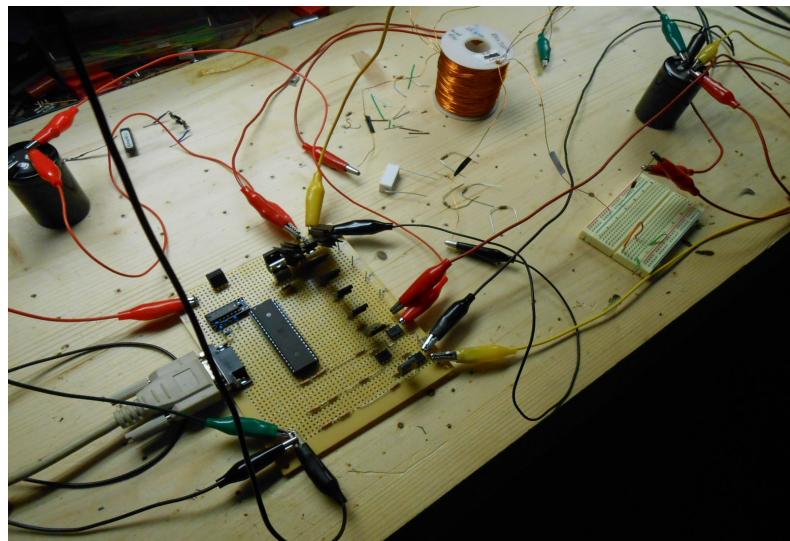

Output joules were calculated by $((D_2 * 0.047) * D_2) / 2 - ((B_2 * 0.047) * B_2) / 2$

D₂ = Output end cap voltage

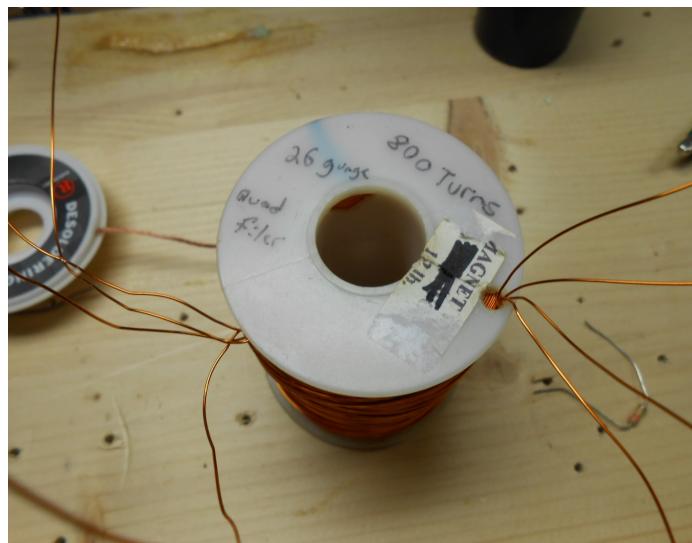

B₂ = Output start cap voltage

Tests:

Comparisons per core are at the end of each core run and comparisons of cores are at the very bottom of pdf.

Ferrite

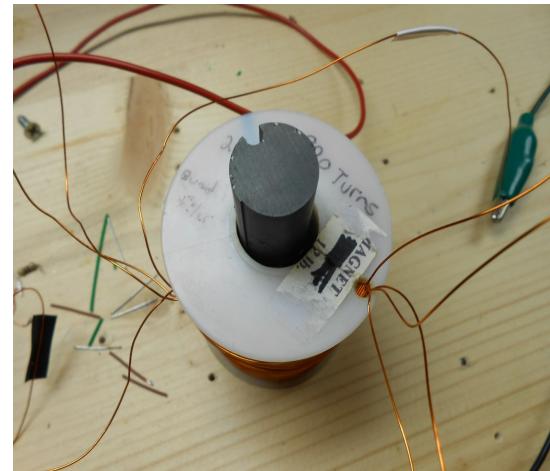

The only ferrite I could find to mostly fit the core was from a flyback core.

So I used a dremel to cut the ends off.

It kinda broke evenly after I cut a grove around it.
